

DEM Part Number 902/3 - 144H_____

90_____ **MHz. Transverter,** _____ **MHz IF, SN**_____

Power Out Maximum:	30 W linear	60 W linear
Noise Figure and Gain:	1.5 dB maximum @ 17 dB conversion gain	
DC Power Requirement:	11.5 - 15.5 VDC @ 10 Amp	20 Amp
IF Option:	Common	Split
IF Drive Level Range Option:	-20 dBm to +0 dBm	1-100 mW 100 mW-1W 1-10W
Keying Option:	PTT - to ground	TTL - Positive Voltage
Aux. Connection Output Option:	TX RX High	Low Open
Antenna Option:	Common (optional)	Separate TX & RX
Frequency Offset:	_____ kHz.	

Operational Overview

The DEM 902/3 -144H is a high power 33 cm to 144 MHz transmit and receive converter. It has linear output power of 30 or 60 watts and depending on the drive level option chosen, it may be achieved with as little as -20 dBm mW or a maximum of 10 W. This transverter is a combination of our standard 33 cm transverter and one of our new 33 cm power amplifiers. The transverter's receive section uses a PHEMT that has a high-pass tuned input circuit biased for High IP3 output performance. It is followed by two helical filters, a high output IP3 MMIC gain stage, and a high level mixer with an IP3 output of +30 dBm. This design provides a sensitive low noise receiver with superior out of band signal rejection that will tolerate IP3 input signals > +5 dBm! The base oscillator of the local oscillator circuit is housed in a shielded enclosure on the circuit board. This shield coupled with the higher frequency base oscillator operation reduces the amount of spurious output while providing greater temperature stability. The transmit section has helical filtering to eliminate the troublesome LO and most spurious emissions. The two different power levels are achieved by MOS-FET hybrid power modules. The high power transverter can be configured for a common antennae or separate TX and RX connections. Auxiliary external switching connections are standard for DC switching of high power amplifiers, preamplifiers, or TR relays. The 144 MHz IF levels and options are adjustable on both transmit and receive with a dynamic range of approx. 20 dB. This adjustment combined with the relative power meter is useful for adjusting your maximum output power or setting the "S" meter level on your IF receiver. Options have been provided for a key line input PTT-H (+1 to 15 VDC) or PTT-L (a closure to ground). The PTT and auxiliary connections are via RCA jacks. The IF connections are via BNC connectors. The 33 cm connectors are Type 'N' only. The enclosure and heat sink for both models measure approximately 3.5 " high by 7 " wide by 9.75 deep and are painted in our standard rugged gray.

Rear Panel view

Connect your transceiver to the transverter:

Interfacing the transverter to the transceiver is easy. First, review the front page configuration. If the transverter was configured for direct connection to your transceiver, (10 watts or less) follow the steps listed below. If you plan to use this transverter with any of the DEMI transverter interfaces, follow the set-up instructions of that interface. If you have ordered a custom interface configuration, you already have an idea of what you are doing. Therefore, use the directions listed below as a guideline.

1. Connect all IF cables. The transverter may have a common IF port or two separate ports, TXIF and RXIF on the IF connector. Use good quality coax cable to connect the 144 MHz. ports between your transceiver and the IF connectors on the transverter.
2. Connect the "Push-to-Talk" line out of your transceiver to the transverter. It is a RCA connector labeled PTT on the transverter. Refer to the configuration sheet for the type of keying required.
3. If separate TX and RX ports were ordered, the internal transfer relay option has not been installed. The separate ports are labeled TX and ANT/RX. If you have the antenna relay option installed, the "ANT/RX" port has both TX and RX functions. Connect your 33 cm antenna system or a dummy load with a power meter to the appropriate 33 cm transverter ports.
4. Connect the DC POWER to the transverter. It uses a AMP type connector and is supplied with the matching cable. 13.8 volts is optimum but the transverter will operate normally from 11 to 15 volts. It has a 10 amp requirement for the 30 watt version and a 20 amps for the 60 watt. On the bottom of the transverter, preset the TXIF and RXIF gain controls in the transverter. Turn both controls fully clockwise. This is maximum attenuation on Transmit and minimum attenuation on Receive.
5. Power your transceiver "ON" and leave it in the Receive mode on 28 or 144.100 MHz. This should be 902/3.100 MHz. unless a frequency offset is indicated on the front page or you ordered a non-standard transverter.
6. Observe the noise level in the transceiver. If it is too high, adjust the RXIF gain control counter-clockwise until a slight noise increase is heard in the transceiver or just a slight movement in the "S" meter is detected. Power the transverter on and off to verify the change. The RXIF gain may be increased beyond this point, but it will start to degrade the dynamic range of your transceiver. Its all user preference. Find a signal on the band or use a signal generator to determine correct frequency, or minimum signal level. If you plan to install an external LNA, this level will change.
7. It is now recommended to test the transverter's transmit section in the CW mode because most transceivers have carrier level or power level controls in this mode only. Do not use full or semi break-in if possible. Do not use FM, SSB or AM because it may not be possible to obtain

maximum output power with a transceiver in these modes. Set the carrier/output power control to minimum or "0" output power. Place the transceiver into transmit. If the PTT circuit is connected correctly, the transmit LED on the transverter will switch on. While observing the built in relative power meter or a 33 cm RF power meter, slowly increase the carrier control (with key down) or increase the power output control to the maximum IF drive level obtainable by your transceiver. If this is not what is indicated on the front page of this document, do not exceed that level by more than 20 % or if you find that the transverter is not correctly set-up for your transceiver's range, go to the "IF Options" section at the end of this page and re-configure the transverter before further testing.

If the transverter is configured correctly for your transceiver, minimal power may be detected on the power meter. Now slowly adjust the TXIF control in the transverter in a counter-clockwise direction while observing the power meter. Set it to any desired level between 0 and the maximum specified output power. The relative power meter is set to show 9 bars lit for the specified output power. This may vary with a bad VSWR but will be true into a 50 ohm dummy load. Switch the transceiver to USB and make a transmission. The power output and current drain should correlate to your speech pattern.

8. You may re-adjust both RXIF and TXIF again if desired. The receive amplifier and local oscillator frequency should not need to be adjusted but you may if you wish. Do not adjust any of the helical filters unless you have access to a spectrum analyzer at the minimum.
9. Your transverter system is ready to use. Connect as you wish to use it in your 33 cm system and have fun!

DEM 902/3 - 144 User Options and performance Improvements:

PTT options:

Both PTT-H and PTT-L can be changed on the topside of the board. The connections are located in the center of the board near the connector panel. Change the jumper as required from the PTT connection to either "L" (Ground to transmit) or "H" (Apply positive voltage to transmit)

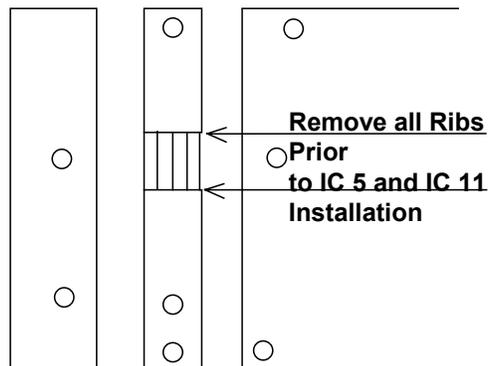

Add an external preamplifier for noise figure improvement:

If a better noise figure is desired, simply placing a LNA with a modest gain at the antenna will solve that problem. Understand that the addition of gain in front of this stock transverter will degrade the IMD performance, and reduce the dynamic range of the transverter by more than the amount of gain added. You may get away with doing nothing more than adjusting the RXIF gain control if you operate in a non-hostile RF environment. If your LNA is a ultra low noise unit, it most likely will not have the IP3 performance the transverter has. It will overload before any component in the transverter will. So, your receive system now becomes limited by it's external LNA's performance. If you increase the gain performance of your external LNA, (25-30 dB) you may consider bypassing the transverters LNA completely because it's IP3 performance is totally controlled by the external LNA. To do so, remove L31, R31, and R30 from the circuit. Then remove the RX coax from the input position and connect the center conductor to the pad of C63. Be sure to keep it as short as possible and solder the shield to ground.

Install / Remove RXIF and TXIF gain stages:

It is better not to use IC5 in the circuit than to add it and increase the attenuation of the RFIF gain control. But, for whatever reason, you may require additional gain or have too much IF gain if IC5 was installed, IC5 can be installed or removed at any time. Be sure of your systems performance when deciding to make a change. You are also not limited to the specified ERA6 MMIC. The ERA6 was chosen for it's IP3 output performance. Using this MMIC doesn't degrade the transverters overall performance unless a external LNA is added into the system. **A higher gain MMIC will reduce the IP3 by the difference in gain and degrade the systems IP3 output performance.** In the future, this MMIC type may change as better devices become available. If installing the MMIC, be sure to add or remove the correct choke and bias resistor for the desired MMIC. Cut the ribs in the circuit if required. If removing, replace the circuit board opening with a large value capacitor. The RXON signal is the input voltage of the transverter (13.8VDC) so calculate the new bias resistor based on that voltage.

Only install IC11 if your TX drive level is less than 1 mW. If you elect to install IC11, the modification must be performed to the printed circuit board. Referring to the diagram above and the assembly document, remove the "Ribs" by cutting at the two indicated points with a sharp razor blade and heating with a soldering iron to remove. Proceed to install IC11 using the component placement and component list.

Add an external power amplifier:

There are different means in which this can be implemented. First, determine if your transverter has a common or split RF ports. To add a power amplifier to a common port transverter will require two additional relays on the input and output of the amplifier to allow the receive signals to bypass the added power amplifier. If your transverter has separate RX and TX ports, you can add the power amplifier in the TX path and install one relay on the output. This option can be the least troublesome (less relays) and most cost effective. If you wish to change your transverter from a common to a split RF version, a TX connection may be installed directly to the PA section of the transverter with a connector installed in the rear panel or the transverter may be returned to the factory for the modification. Also, consider using additional filtering or adding an isolator to the system between the transverter and power amplifier for gain and spurious management.

Auxiliary switching contacts:

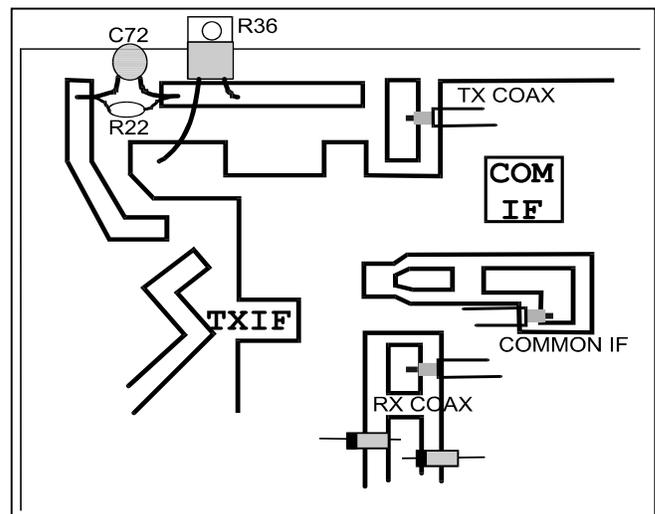

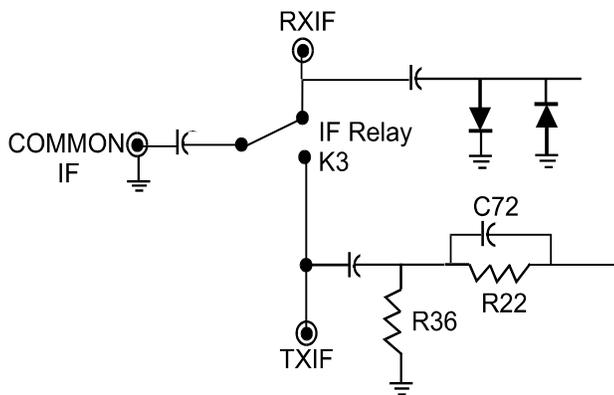

The auxiliary contacts in the transverter are wired as indicated on the front page. Referring to the component placement and schematic, relay K2 is labeled C (common) NO (normally open) and NC (normally closed). The contacts are marked for the receive mode. The C connection can be wired to ground or positive voltage such as the source +13.8 VDC. The K2 common connection will then be toggled depending on what state the transverter is in. The NO or NC can be wired to the AUX connector on the enclosure for keying additional power amplifiers, relays and other equipment in your system. The contacts are rated for 3 Amps @ 24 VDC

IF options:

The IF configuration of this transverter is listed on the front page. If you desire a different configuration, it may be changed. All possible IF configurations are shown below in the supplied schematic and simplified component layout. Follow the schematic and parts matrix list for desired drive level ranges if you require a different configuration or drive level. Splitting the IF to separate TX and RX is diagramed in the simplified component layout below. Other combinations and drive levels may work but do not exceed 10 Watts of drive level! The 50 Ohm load is rated for 30 watts but only on a heat sink.

144 MHz. IF Configurations

	-20 dBm to 0 dBm	1-200 mW Drive	200 mW-1W Drive	1-10W Drive
C72	Not Installed	Not Installed	Not Installed	1pF
R36	Not Installed	Not Installed	50Ω, 30W	50Ω, 30W
R22	Replace with short	220Ω, 1/4W	220Ω, 1/4W	Not Installed

Common or Split IF Configuration

Amplifier Section

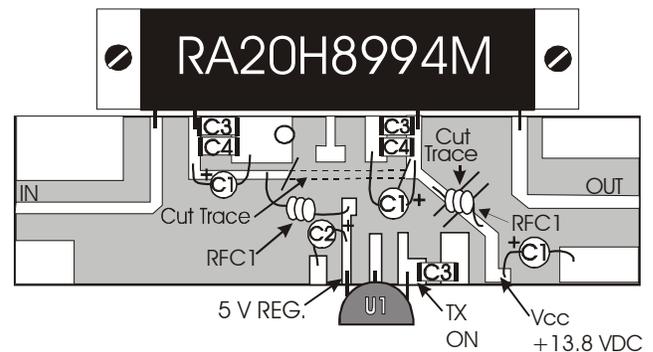

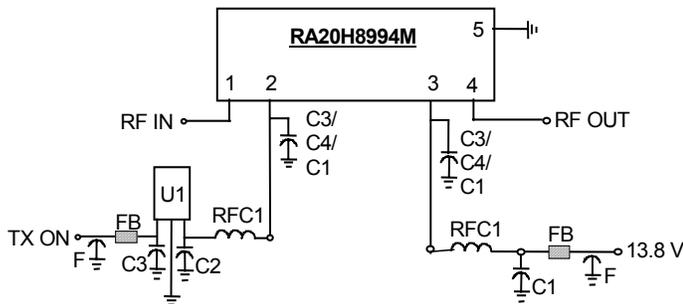

The amplifier section is shown below as the 30 watt version. For the 60 watt unit, duplicate the components listed below. There may be additional grounding built into the PCB. There may also be a shield attached. The single hybrid will require 5 mW from the transverter board to achieve the HP transverters rated output power. For this reason, there may be an additional attenuation installed on the transverter board. This will depend on the gain of the RA20H8994M hybrid. They vary as much as 10 dB! Additional RF circuit adjustments to the power amplifier circuit may have been made to increase output power, improve input matching, or increase DC power efficiency. Additional beads or RF chokes may also be installed.

RA18H1213G Pin Out

1	RF In
2	TXON (Bias)
3	13.8VDC (VCC)
4	RF Out
5	RF & DC ground (Flange)

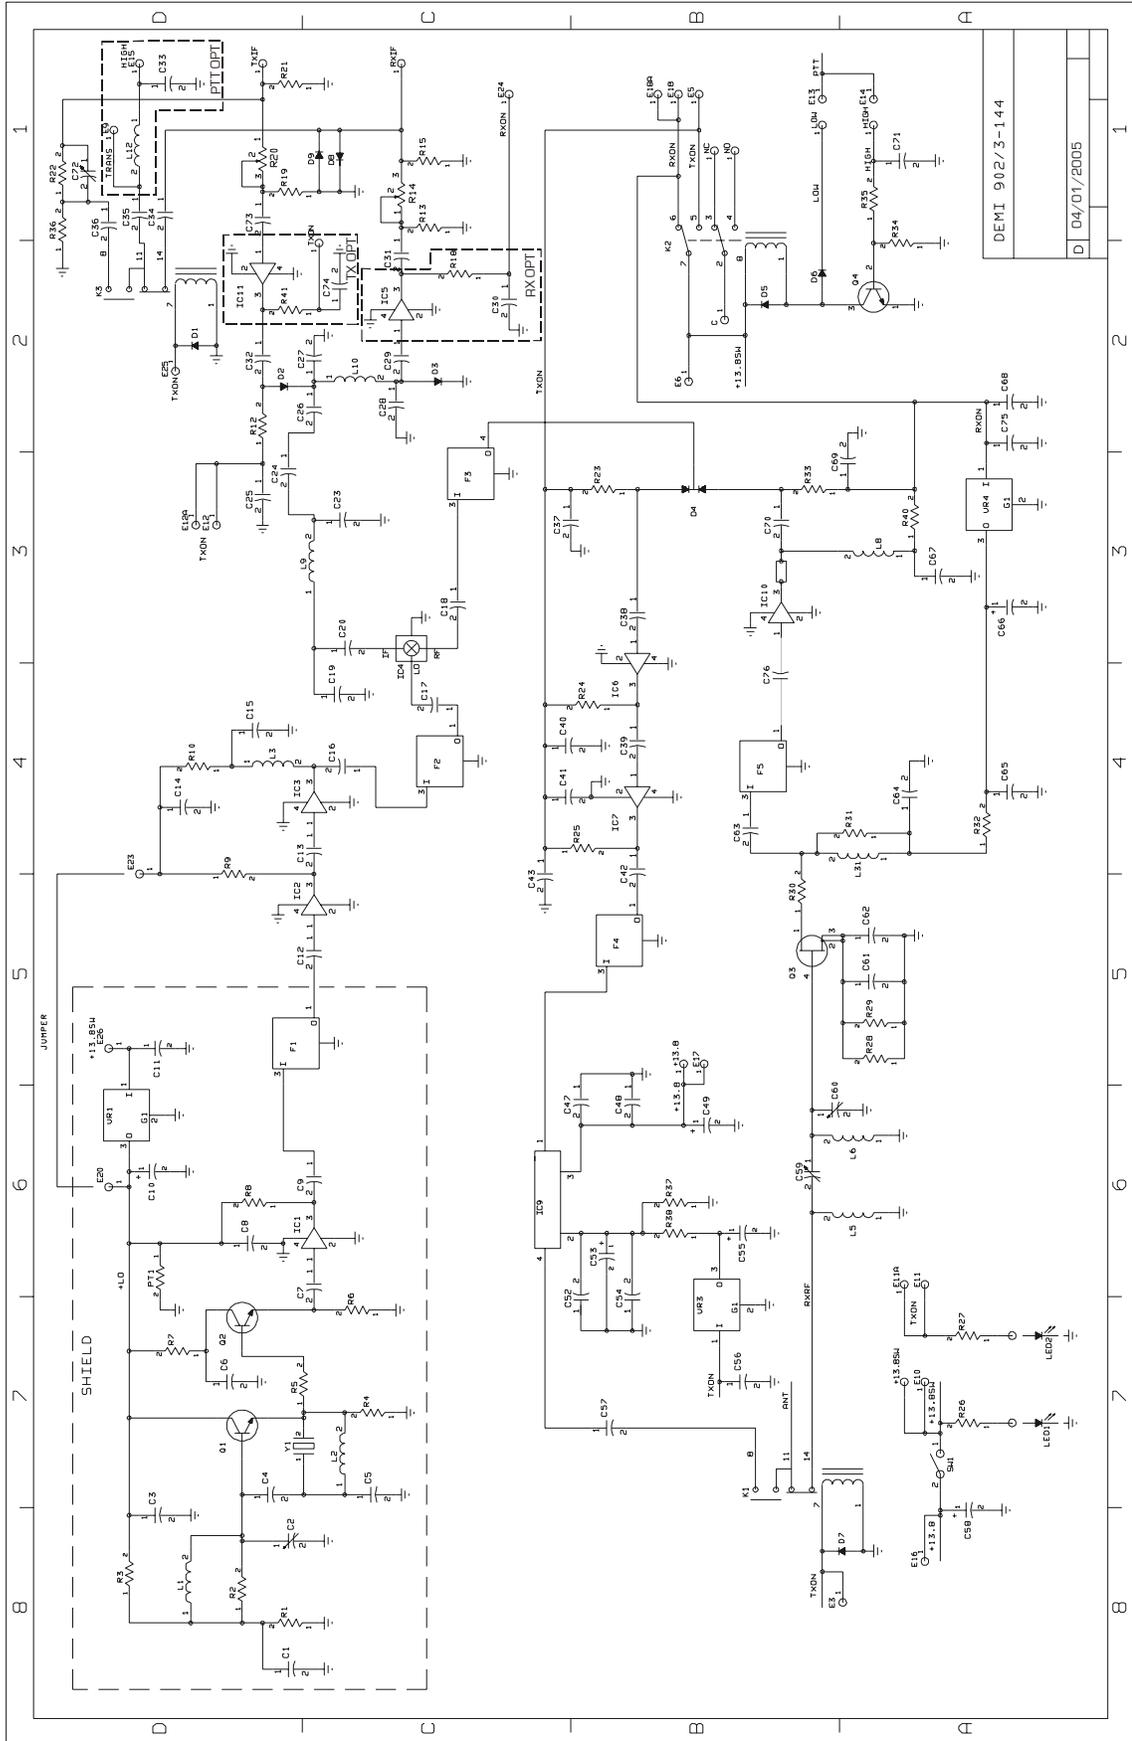

Component List

	Qty.	Description
C1	2	2.2 μ F electrolytic
C2	2	100 μ F electrolytic
C3	2	0.1 μ F chip
C4	2	1000 pF chip
U1	1	78L05 regulator
	1	RA20H8994M

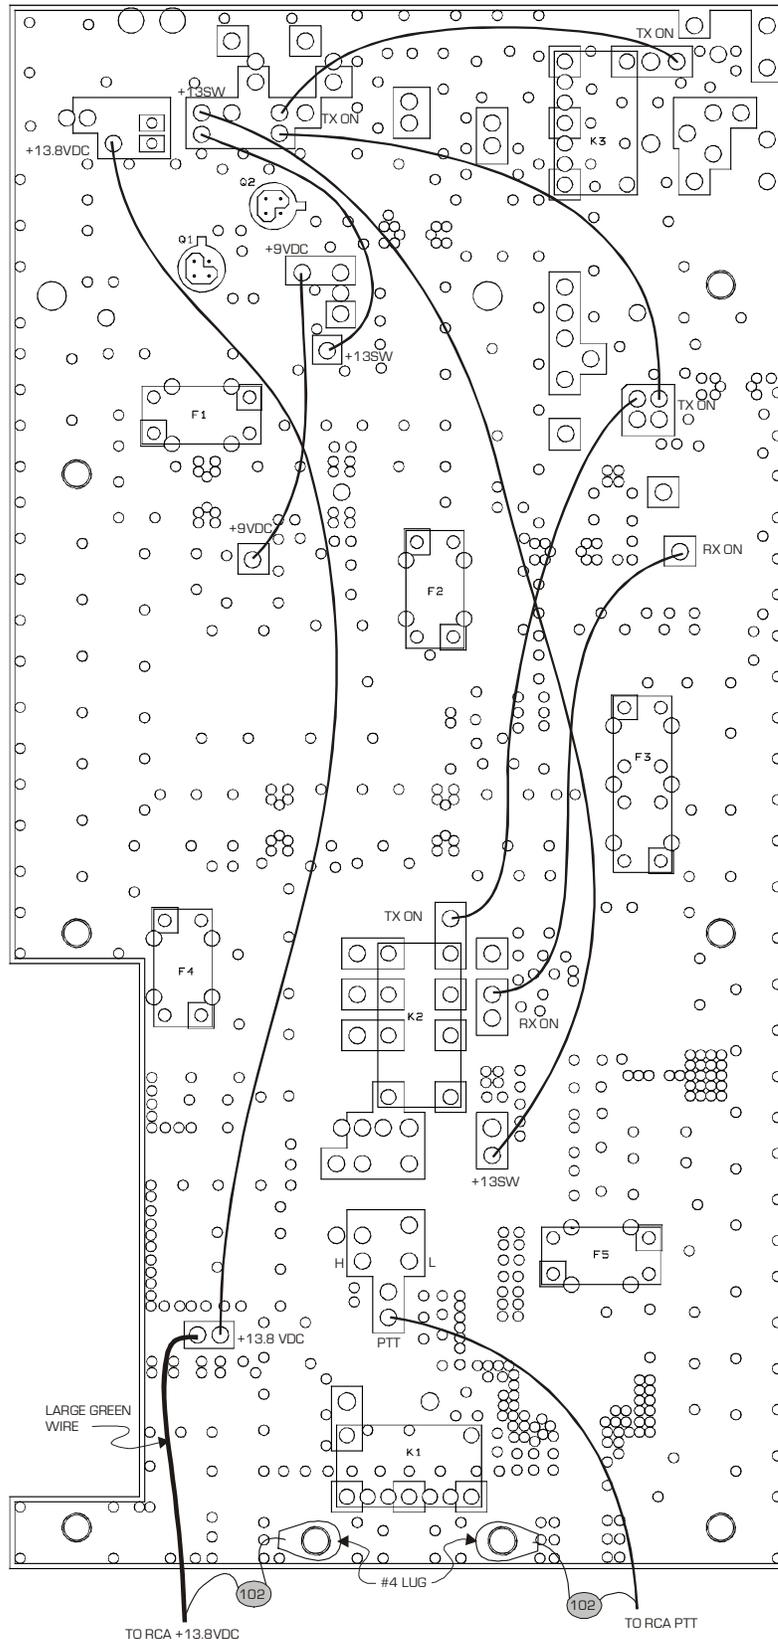

50 Watt Version

The additional components required for the 50 watt version are 50 ohm loads and two "wire line" combining circuits. The loads may be single piece units or made up of chip resistors. The circuit board will look different but are electrical the same with the accommodating pads to install the wire line combiners and loads. Additional circuit adjustments may have been made for grounding and overall performance.
